

6161

UHF POWER TRIODE

**Small Size
Coaxial Elec-
trode Structure**

**Forced-Air-Cooled, Grounded-Grid Type
400 Watts CW Input to 900 Mc
250 Watts CW Input at 2000 Mc**

**3-13/32" Max. Length
1.760" Max. Diameter
Integral Radiator**

TENTATIVE DATA

RCA-6161 is a very compact, forced-air-cooled power triode of the grounded-grid type designed for uhf service in television and cw applications.

It has a maximum plate dissipation of 250 watts in cw and television service. The 6161 can be operated with full plate voltage and plate input at frequencies as high as 900 Mc, and with reduced ratings up to 2000 Mc.

rf electrode terminals for insertion into the cylinders, and permits effective isolation of the plate from the cathode. The latter feature makes the 6161 particularly suitable for grounded-grid circuits.

The 6161 supersedes the type 5588 for new equipment design.

GENERAL DATA

Electrical:

Heater, for Unipotential Cathode:		
Voltage (AC or DC)*	{ 6.3 av.	volts
	{ 6.9 max.	volts
Current	3.4	amperes
Minimum Heating Time	1	minute
Amplification Factor	27	
Direct Interelectrode Capacitances:		
Grid to Plate	6	$\mu\mu\text{f}$
Grid to Cathode	11	$\mu\mu\text{f}$
Plate to Cathode	0.32 max.	$\mu\mu\text{f}$

Mechanical:

Mounting Position	Any
Overall Length	3-5/16" \pm 3/32"
Greatest Diameter	1.750" \pm 0.010"
Radiator	Integral part of tube
Mounting	Special

Air Flow:

The specified air flow for various plate dissipations, as indicated in the tabulation below, should be delivered by a blower onto the respective terminals and seals, and through the radiator before and during the application of any voltages. Heater power, plate power, and air may be removed simultaneously.

Percentage of Max. Rated Plate Dissipation for Each Class of Service			
100	80	60	per cent
16	10	5.7	cfm
0.85	0.4	0.16	in. of water

The above flow and pressure values are for condition with radiator temperature held constant at 135°C rise above incoming-air temperature. The air flow must be adequate to limit the temperature of the radiator, grid terminal, cathode terminal, and seals to their respective maximum values.

Incoming-Air Temperature	45 max.	°C
Radiator Temperature (Measured on core at end adjacent to plate ring)	180 max.	°C
Grid-Terminal Temperature	150 max.	°C
Cathode-Terminal Temperature	150 max.	°C
Seal Temperature (Plate, grid, and cathode)	150 max.	°C
Weight (Approx.)	8	ounces

RF POWER AMPLIFIER--Class B Television Service

Synchronizing-level conditions unless otherwise specified

- Note 1: With 6.3 volts ac on heater.
 Note 2: With dc grid voltage of -15 volts, and dc plate voltage adjusted to give dc plate current of 250 ma.
 Note 3: With external shield, as described under (♦) connected to grid terminal.
 Note 4: With dc grid voltage of -10 volts, and dc plate voltage adjusted to give dc plate current of 250 ma.
 Note 5: With dc grid voltage of -20 volts, and dc plate voltage adjusted to give dc plate current of 250 ma.
 Note 6: With dc plate voltage of 1600 volts, and dc grid voltage adjusted to give dc plate current of 1.0 ma.
 Note 7: Designers should limit the maximum useable cathode current (plate current and grid current) to this value under any condition of operation.
 Note 8: In a self-excited oscillator circuit and with dc plate voltage of 1600 volts, dc plate current of 250 ma., dc grid current of 50 to 75 ma., grid resistor of 2000 \pm 10% ohms, and frequency of 15 Mc.

- * Because the cathode is subjected to considerable back bombardment as the frequency is increased with resultant increase in temperature, the heater voltage should be reduced depending on operating conditions and frequency to prevent overheating the cathode and resultant short life.
- ♦ With external flat shield 7-1/2" min. diameter located in plane of the grid terminal and perpendicular to axis of tube. Shield is connected to grid terminal.
- Continuous Commercial Service.
- Computed between half-power points and based on tube output capacitance only.
- The driver stage is required to supply tube losses, rf circuit losses, and rf power added to plate input. The driver stage should be designed to provide an excess of power above the indicated value to take care of variations in line voltage, in components, in initial tube characteristics, and in tube characteristics during life.
- # This value includes 24 watts of circuit loss and 36 watts added to plate input.
- This value of useful power is measured at load of output circuit having indicated efficiency.
- This value includes 28 watts of circuit loss and 40 watts added to plate input.
- ** This value includes 18 watts of circuit loss and 40 watts added to plate input. In grounded-grid, plate-modulated class C rf power amplifier service, the 6161 can be modulated 100% if the rf driver stage is also modulated 100% simultaneously. Care should be taken to insure that the driver-modulation and amplifier-modulation voltages are exactly in phase.
- This value includes 23 watts of circuit loss and 40 watts added to plate input.

- Key-down conditions per tube without amplitude modulation. Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115% of the carrier conditions.
- ▲ This value includes 18 watts of circuit loss and 45 watts added to plate input.
- † This value includes 23 watts of circuit loss and 45 watts added to plate input.

OPERATING CONSIDERATIONS

The maximum ratings shown in the tabulated data are limiting values above which the serviceability of the 6161 may be impaired from the viewpoint of life and satisfactory performance. Therefore, in order not to exceed these absolute ratings, the equipment designer has the responsibility of determining an average design value for each rating below the absolute value of that rating by an amount such that the absolute values will never be exceeded under any usual conditions of supply-voltage variation, load variation, or manufacturing variation in the equipment itself.

The maximum radiator temperature of 180°C as well as the maximum terminal and seal temperatures of 150°C are tube ratings and are to be observed in the same manner as other ratings. The temperature of the radiator should be measured on the core at the end adjacent to the plate ring (see *Outline Drawing*). The temperature may be measured either with a thermocouple or with temperature-sensitive paint, such as Tempilaq. The latter is made by the Tempil Corporation, 132 W. 22nd Street, New York 11, N.Y., in the form of liquid and stick, and is stated by the maker to have an accuracy of 1 per cent.

In transportation and storage of the 6161, care should be taken to protect the tube from rough handling that would damage the glass-to-metal seals or dent or mar the rf contact surfaces. Particular care should be taken not to subject the tube to severe shock which might permanently deform the internal elements. It is recommended that the tube be tested upon receipt in the equipment in which it is to be used.

The mounting may be arranged to support the 6161 in any position. The tube may be supported by the plate ring or by the radiator in any convenient way, but the mounting arrangement used must not subject the grid, cathode, and heater terminals to undue stress.

Because the terminals of the 6161 have progressively smaller diameters from plate to grid to cathode to heater as shown in the *Outline Drawing*, it is possible to insert the 6161 into coaxial and cavity circuits from one end without disassembly of the circuit. In such circuits, the 6161 is supported by the plate ring as shown in Fig. 1.

In the design of this mounting, it is to be noted that the hole in part A, which limits movement of the tube in directions parallel to the plate contact surface, is approximately 0.050"

larger than the maximum diameter of the plate ring in order to allow the tube to seek its position freely when being inserted into the grid, cathode, and heater contacts, and to seat properly on the plate contact surface of part B. After the tube is in place, the removable clamp C is brought into position and closed to make the plate contact secure and to anchor the tube firmly in place.

Fig. 1 - Mounting Arrangement for Use with Coaxial-Line or Cavity Circuits.

In addition to the dimensions shown in Fig. 1, the equipment designer should also observe the diameter tolerances on the grid, cathode, and heater terminals and the limits on concentricity defined by the gauge (see *Outline Drawing*) in order to provide for variation from tube to tube.

Cooling of the 6161 is accomplished by delivering a stream of clean air from a blower onto the respective terminals and seals, and through the radiator before and during the application of any voltages. The air flow through the radiator may be in either direction. The minimum rate of air flow for various plate dissipation is shown in the tabulated data. A suitable air filter is required in the air supply. Care should be given to cleaning or replacing the filter at intervals in order that accumulated dirt will not obstruct the required flow of air through the radiator. When the 6161 is operated at full ratings, a flow of at least 16 cubic feet per minute at a pressure of about 0.85 inch of water is recommended.

The cooling system should be properly installed to insure safe operation of the 6161 under all conditions and for this reason should be electrically interconnected with the heater and plate power supplies. This arrangement is necessary to make sure that the tube is supplied with air before any voltages are applied. Air pressure interlocks which open the power transformer primary of the heater supply and the plate supply are desirable for protecting the tube when the air flow is insufficient or ceases.

The heater of the 6161 should be operated at constant voltage rather than constant current. The rated heater voltage of 6.3 volts should be

applied for at least 1 minute to allow the cathode to reach normal operating temperature before voltages are applied to the other electrodes.

The *unipotential cathode* is indirectly heated by the heater, one terminal of which is common to the cathode. The cathode of the 6161 in uhf service is subjected to considerable bombardment resulting from transit-time effects. This back bombardment raises the temperature of the cathode. The magnitude of the heating caused by back bombardment is a function of the operating conditions and frequency, and must be compensated by reduction of the heater input in order to prevent overheating of the cathode and resultant short life. When long life in continuous service

Fig. 2 - Average Characteristics of Type 6161.

is desired, the 6161 should always be put in operation with full rated heater voltage (6.3 volts) which should then be reduced to the lowest

value that will give the desired power output. Because the cathode of this tube when operated with a heater voltage of 6.3 volts provides emission usually in excess of any requirements within ratings, it is recommended that the heater voltage be reduced below 6.3 volts to a value that will give adequate but not excessive emission from the cathode for any particular application. The proper operating value may then be found by reducing the heater voltage, with normal modulation applied to the transmitter, until a reduction in output is observed. The heater voltage must then be increased by an amount equivalent to the maximum percentage regulation of the heater-voltage supply, and then further increased by about 0.1 volt to allow for other variations. After the heater voltage is reduced, circuit re-adjustment may be necessary. It is suggested that the adjustment procedure be carried out daily. However, if no significant changes in the operating voltage are found necessary, the adjustment procedure can be scheduled less frequently. Good regulation of the heater voltage is in general economically advantageous from the viewpoint of tube life.

The *grid* of the 6161 in uhf service is subjected to heating caused not only by the normal electron bombardment as indicated by the grid

current, but also by bombardment due to transit-time effects and by circulating rf currents. For these reasons, more than ordinary care must be taken during operation to prevent overloading the grid.

The *plate* should be protected against overload. The protective device, such as a fuse in the plate circuit, should remove the dc plate voltage when the average value of plate current reaches a value 50% above normal.

Average characteristics for the 6161 are shown by the curves in Fig.2.

In *tuning a grounded-grid rf amplifier*, it must be remembered that variations in the load on the output stage will produce corresponding variations in the load on the driving stage. This effect will be noticed by the simultaneous increase in plate currents of both the output and driving stages.

During *standby periods* of less than 15 minutes, it is recommended that the heater voltage be reduced to 80% of normal to conserve life; for longer standby periods, the heater power should be turned off.
